

Click Chemistry

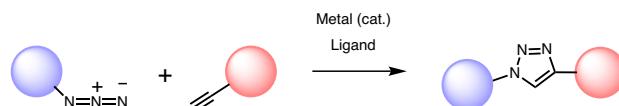

Click Chemistry

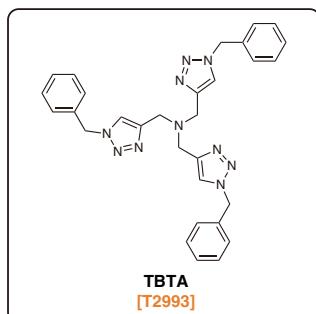

"Click Chemistry" is a term which was first described by K. B. Sharpless in 2001 to describe reactions that afford products in high yields and in excellent selectivities by carbon-hetero bond formation reactions. The term "Click" means joining molecular pieces as easily as clicking together the two pieces of a seat belt buckle. In general, the definition of click chemistry is described as follows:

1. give very high chemical yields of desired products
2. combination of readily available simple building blocks
3. generate almost no byproducts
4. simple product isolation by non-chromatographic methods
5. reaction proceeds in water, as well as in organic solvents

While there are a number of reactions that fulfill this criteria, the Huisgen 1,3-dipolar [3 + 2] cycloaddition¹⁾ of azides and alkynes has emerged as the frontrunner. In general, the 1,2,3-triazole ring is not almost oxidized or reduced, which makes it possible to strongly connect two substrates.

In the Huisgen reaction, metal catalysts, such as copper sulfate, are generally required for reaction acceleration. In especial, it has been reported that the combination of tris[(1-benzyl-1*H*-1,2,3-triazol-4-yl)methyl]amine (TBTA) [T2993] and catalysts shows excellent reactivity.²⁾

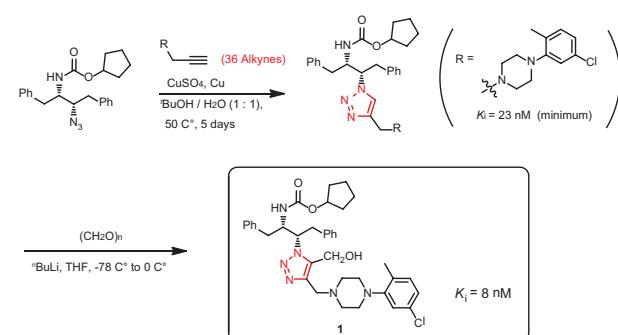

This reaction system affords desired products in almost 100% yield with no need of repurification, such as recrystallization or column chromatography. Thus, this methodology is an eco-friendly reaction. Moreover, the combination of various alkynes and azides allows it to rapidly construct large compound libraries, and 1,2,3-triazole itself exhibits various kinds of biological activities, such as anti-allergenic or anti-bacterial activities. In addition, the reaction proceeds even in water, and thus, click chemistry has been widely used in many research fields as below.

● Research of Various Pharmaceutical Lead Candidates

a) Application of Anti-HIV Agent Discovery³⁾

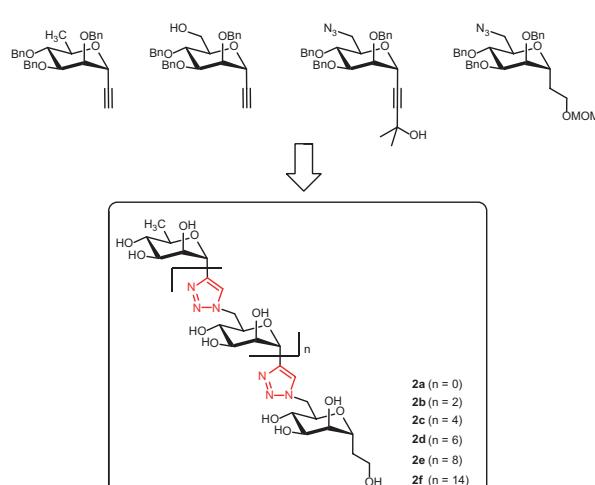

Whiting and Sharpless *et al.* have reported the synthesis of a series of 1,4-disubstituted-1,2,3-triazoles as potential candidates for HIV protease inhibitors in a combination of azide-containing fragments with a diverse array of functionalized alkyne-containing building blocks by using click chemistry. After further optimization, it was revealed that **1** has the highest activity, exhibiting 8 nM of K_i value.

b) Research of Mycobacterium Tuberculosis

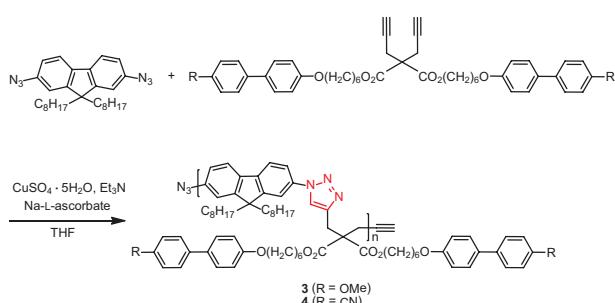

Cell Wall Synthetase⁴⁾

Dondoni *et al.* have reported the synthesis of a set of C-oligomannosides (**2a-f**) through click chemistry using a 1,2,3-triazole ring as the interglycosidic linker. The compounds **2a-f** inhibit mannosyltransferases, which are involved in the biosynthesis of the cell envelope of *Mycobacterium tuberculosis* cell wall synthase. Among them, the hexamer ($n = 4$) **2c** and octamer ($n = 6$) **2f** show the highest activities $IC_{50} = 0.14$ and 0.22 mM, respectively.

● Synthesis of Functional Materials

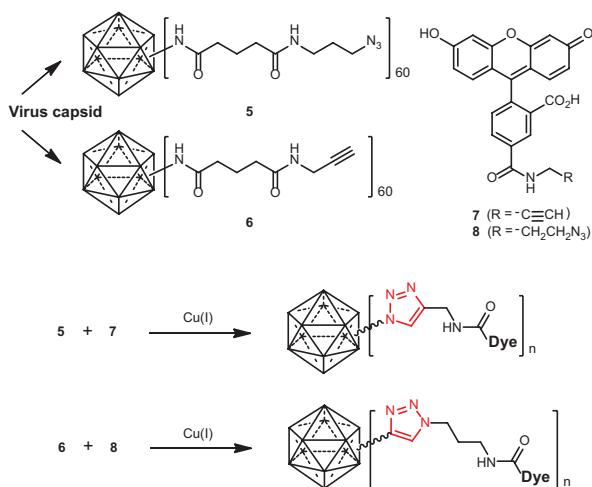

Click chemistry has been also successfully applied into polymer synthesis or material science. For example, Kang and Jin *et al.* have reported the synthesis of side-chain liquid-crystal polymers **3** and **4** by using click chemistry. According to their results, the dye-sensitized solar-cell fabricated from **3** gives a power-conversion efficiency of 4.11%.⁵⁾

● Bioscience

Bioconjugation (example: surface modification of virus)⁶⁾

In general, viruses are made up of a number of protein subunits, and capsids, which enclose DNA or RNA, are formed as protein shells. In particular, in the case of spherical viruses, the capsids have an icosahedral symmetry form with sixty protein subunits. Finn and Sharpless *et al.* have reported the modification of the exterior surface of a spherical virus, *cowpea mosaic virus* by azides or alkynes, followed by the labeling of these species using fluorescein dye-azide or alkyne by click chemistry.

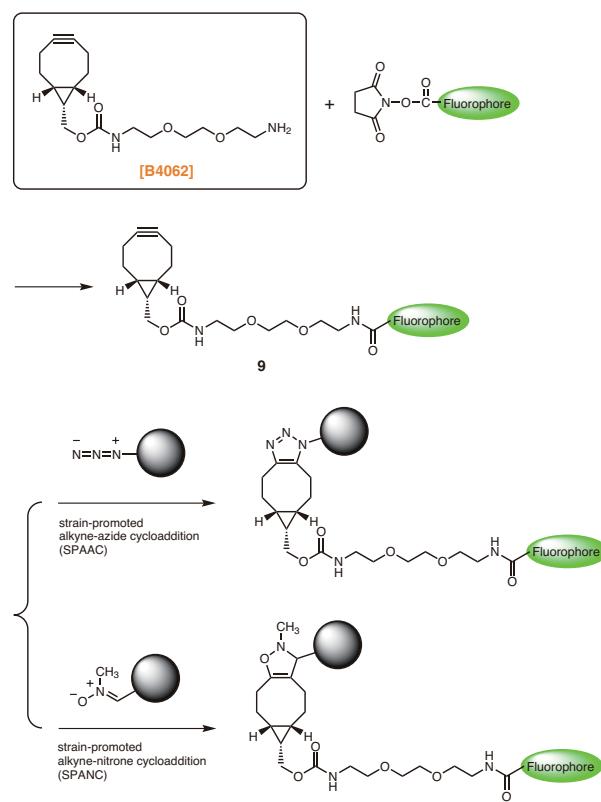

Thus, click chemistry has been widely used as a methodology of synthesizing novel molecules in a number of research fields. Other than these applications, click chemistry also has been applied in various fields, such as the synthesis of dendrimers,⁷⁾ dendrons,⁸⁾ calyxarenes,⁹⁾ rotaxanes,¹⁰⁾ catenanes,¹¹⁾ the development of chemical sensors,¹²⁾ and the labeling of DNA.¹³⁾

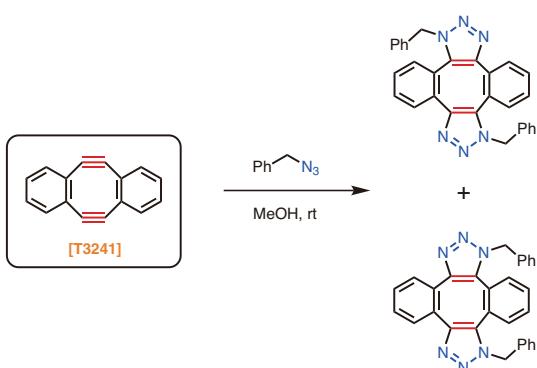

● Copper-free Click Reaction

As described above, click chemistry also has been used for imaging labeling and tracking labeling of biomolecules. However, the reaction is not suitable for labeling of living systems because it needs a highly-concentrated copper(I) species, thus, bioorthogonal reactions such as metal-free click chemistry also have been developed.

N-(1*R*,8*S*,9*s*)-bicyclo[6.1.0]non-4-yn-9-ylmethyloxycarbonyl-1,8-diamino-3,6-dioxaoctane (BCN-amine) [**B4062**] is a linker having a strained structure with cyclooctyne, and it is used for the copper-free click reaction to azides. For example, **B4062** bonded to a fluorophore (**9**) has resulted in labeling of an azidohomoalanine-containing virus capsid protein without copper(I) species.¹⁴⁾ In addition, **B4062** can be applied to not only strain-promoted alkyne-azide cycloaddition (SPAAC)¹⁵⁾ but also strain-promoted alkyne-nitrone cycloaddition (SPANC).¹⁶⁾

Additionally, Hosoya *et al.* have reported the “double-click reaction” applying 5,6,11,12-tetrahydrobenzo[a,e]cyclooctene [**T3241**]¹⁷⁾ in click chemistry. The high reactivity of the two alkyne moieties allows the reaction to proceed smoothly without using metal catalysts, such as a copper salt.¹⁸⁾

Metal-Free Double-click Reaction

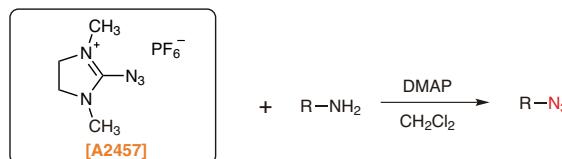

Chiba *et al.* have reported a new click reaction using *N*-succinimidyl 4-(azidosulfonyl)benzoate [**S0973**] and *N*-(1-Thioxoethyl)glycine [**T3312**.²⁴⁾ This reaction needs no metal ion species, and the sulfonyl azide group of **S0973** and thioamide group of **T3312** reacts to form the sulfoamidine moiety. Furthermore, the reaction proceeds at room temperature in water and is applicable to the biorthogonal click reaction.

TCI offers a variety of azide and terminal acetylene compounds readily available in the field of click chemistry as below. In addition, azidation and ethynylation reagents are also listed in this brochure.

● Azidation Reagent

Organic azide compounds can be synthesized in a simple manner by the reaction of sodium azide with halogenated alkyl compounds, or the reaction with trifluoromethanesulfonyl azide and primary amines, however, these azide sources potentially have highly explosive character, which makes it difficult to handle. 2-Azido-1,3-dimethylimidazolinium hexafluorophosphate [**A2457**], which was developed by Kitamura *et al.*, is a crystalline diazotransfer reagent having high thermal stability and low explosibility. The differential scanning calorimetry (DSC) experiment of **A2457** has revealed that the exothermic decomposition temperature was approximately 200 °C. Moreover, **A2457** has tested negative for the impact and friction-sensitivity tests.¹⁹⁾

Under basic conditions, **A2457** reacts with several kinds of primary amines in a short time to afford the corresponding diazo compounds in high yields.²⁰⁾ In these reactions, the by-products can be removed by conventional extraction procedures due to their high solubility in water.

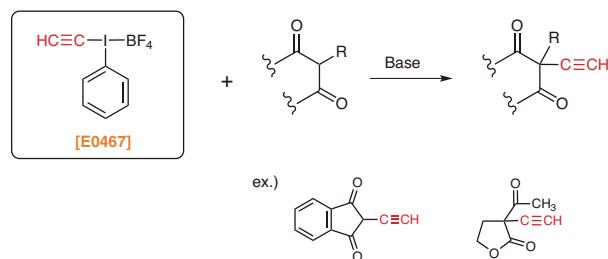

Entry	R	A2457 (eq.)	DMAP (eq.)	Temp.	Time (h)	Yield (%)
1	Ph	1.15	1.1	rt	2.5	87
2	4-MeC ₆ H ₄	1.15	1.1	rt	1.5	94
3	4-AcC ₆ H ₄	1.15	3	50 °C	5	83
4	4-O ₂ NC ₆ H ₄	2	3	50 °C	4	61
5	1-naphthyl	1.3	1.1	50 °C	1.5	92
6	PhCH ₂ CH ₂	1.15	5 ^{a)}	rt	0.25	74
7	1-adamantyl	1.15	1.1	rt	0.33	71

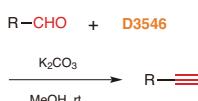

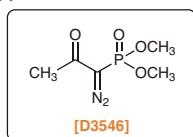

^{a)} Et₃N is used instead of DMAP.

● Ethynylation Reagents

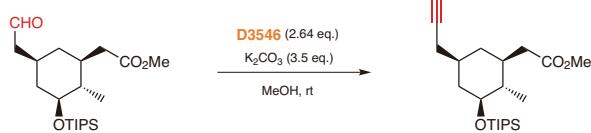

A number of ethynylation reagents have been developed for the synthesis of terminal acetylenes. For example, ethynyl(phenyl) iodonium tetrafluoroborate [**E0467**] is an electrophilic ethynylation reagent developed by Ochiai *et al.*, which reacts with active methylene compounds to afford the corresponding a-ethynylated products in high yields under mild conditions. As for other existing electrophilic ethynylation reagents, ethyl lead triacetate has been exploited, which is prepared from ethynyl(trimethyl)stannane and lead tetraacetate. However, preparation of this reagent requires the use of heavy metal compounds, which make it an unattractive procedure. The ethynylation procedure using this reagent requires careful control of the reaction conditions. The ethynylation method using **E0467** has been at the center of attention in many fields, as this method does not use highly toxic heavy metal compounds, and the reaction proceeds under mild conditions.

Additionally, dimethyl (1-diazo-2-oxopropyl)phosphonate [**D3546**] is a reagent for the synthesis of terminal alkynes, which was developed by Ohira and Bestmann *et al.*^{21,22)} **D3546** reacts with aldehydes in the presence of potassium carbonate and methanol to give the one homologated terminal alkynes in high yields. **D3546** is widely known as the “Ohira-Bestmann reagent” after its discoverers and the reaction proceeds in mild conditions without using strong bases.

(Application 1)²²⁾

$R\text{-CHO}$	Product	Yield (%)
Cl-phenyl-CHO	Cl-phenyl-C≡C	97
OHC-phenyl-CHO	OHC-phenyl-C≡C	74
OHC-thiophenyl-CHO	OHC-thiophenyl-C≡C	80

(Application 2)²³⁾
